

ABSTRACT OF THE DISCLOSURE

The present invention makes it possible to transmit an image, which has been captured as by a digital camera, in the form of a file by facsimile communication. To this end, if an X bit of a FIF (Facsimile Information Field) from a receiving machine is ON, the facsimile apparatus according to this invention judges that the receiving machine has a JPEG-receive function in sYCC color space and a function for receiving an image that has been captured by a digital camera and stored on a memory card. If transmission of image files on a memory card has been specified, the image files on the card are transmitted successively when the X bit of the FIF from the receiving machine is ON. Even if there is a change in number of pixels of file information in the main-scan direction and a color-monochrome change at this time, a PPS-MPS signal is transmitted and the individual image files are transmitted.
